

Workshop constipation

Cristina Nichita
Dieter Hahnloser

Miss GL, 1988

- Consulted in 2011 because of rectal bleeding
- Chronic constipation starting in adolescence, bowel movements every 2-4 weeks, excessive straining, incomplete rectal evacuation
- She takes Movicol 1-2bags/day
- No history of abus, no other medical problems and she is working in a nursery
- Colonoscopy: megadolicocolon with coprostasis in spite of double bowel preparation. Stage II hemorrhoids

Miss GL, 1988

- Biological tests: normal complete blood count, normal ESR, glycemia 4.3 mmol/l, creatinine 76 μ mol/l, normal liver tests, normal thyroid function, normal electrolytes
- She is prescribed 3-4 Movicol bags/day with moderate improvement in constipation and persistence of abdominal bloating and discomfort

**How do you proceed with this patient?
(2011)**

2011

Interview and physical examination

Consider metabolic and structural evaluation, baseline labs

Therapeutic trial-fibers+/-laxatives

Inadequate response

Anorectal manometry , ballon expulsion test

2014-2015:
Linaclotide
Lubiprostone
Prucalopride

Jiang CQ. Int J Colorectal Dis 2008

69.24 mm

Miss GL, 1988

- February 2014: fecal impaction (rectal evacuation under GA) and laparoscopic adhesiolysis
- In March 2014: burning-like abdominal pain and diarrhea (5-6x/day and 1-2/night) and she lost 5 kilos (actual weight: 50.6 Kilos) without nausea, dysphagia or early satiety

→ **Second gastroenterological opinion.
What would you do?**

Second opinion

1. Diagnostic field

- Review of the colonic **histology** confirming the absence of visceral neuropathy or Hirschsprung disease. However an esophageal manometry and a gastric emptying scintigraphy or small bowel manometry could be performed.
- **Colonic transit time**: should be offered after colonic preparation and the segmental repartition should be assessed.
- Proposal to do **anorectal manometry** and **MR defecography**

- Type 2 dyssynergia
- Disorders in rectal sensory function

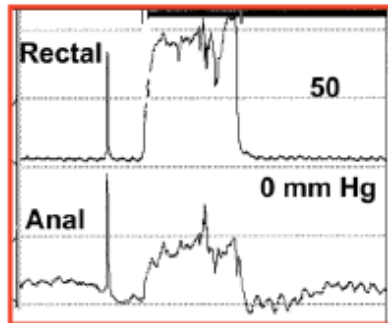

Conclusions:

Colonic inertia secondary to obstructive defecation

Diarrhea secondary to partial colectomy or false diarrhea

Manometric patterns (Rao): attempted defecation

Type I

Type III

Normal

Type II

Type IV

What would you do?

- Failure to open appropriately the sphincter region
- Dyskinesia of the puborectalis muscle
- Inefficient rectal emptying

- Type 2 dyssynergia
- Disorders in rectal sensory function

Conclusions:

Colonic inertia secondary to obstructive defecation

Diarrhea secondary to partial colectomy or false diarrhea

Second opinion

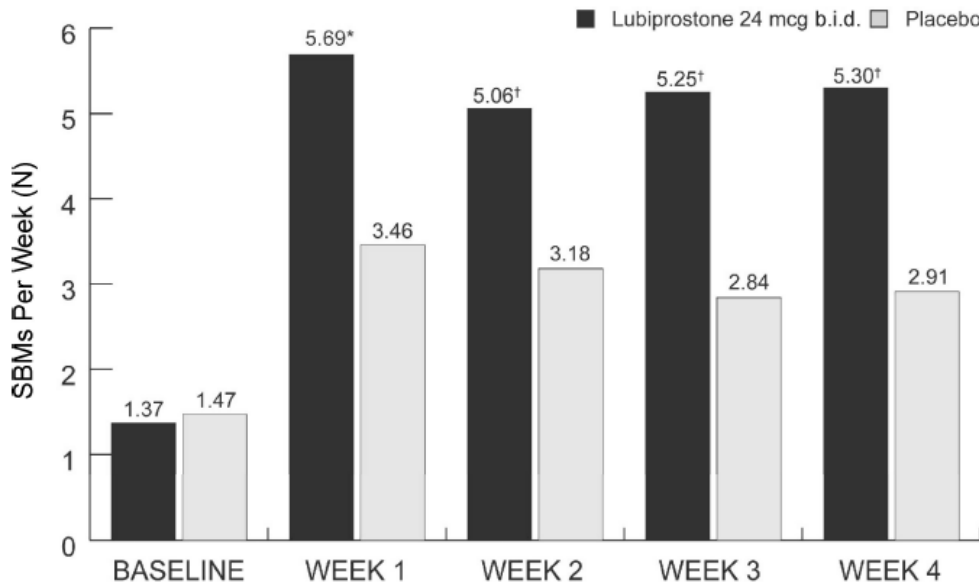

2. Therapeutic field

- Biofeedback
- Botox injections in the puborectalis muscle

Miss GL, 1988

- Constipation starts again in June 2014 with 1 bowel movement/week, excessive straining and abdominal discomfort.
- She starts **Amitiza** 1x/day, than 2x/day and with occasionally Clyssie enema
- She starts **biofeedback** in October 2014
- In December 2014: she is well taking Amitiza 3x/day (occasionally enema) and she is still doing physiotherapy

Amitiza = Lubiprostone

Amitiza =Lubiprostone

- In rats and humans, lubiprostone contracts stomach longitudinal muscle and inhibits neuronally mediated contractions of colon circular muscle (Bassil AK et al. Br J Pharmacol 2008;154:126-135)
- Tested up to 52 weeks in IBS with constipation ($8\mu\text{g}\times 2/\text{day}$) showing significant improvement in abdominal pain and bloating
- Side effects: nausea (take it with meal) and diarrhea
- Also indicated for opioid-induced constipation

What should we do differently next time?

- Other laxative trials before considering surgery
- Complete constipation work-up before surgery (anorectal manometry, defecography, adequate colonic transit time, investigation of the upper gastrointestinal tract to consider)
- Complete treatment of obstructive defecation before surgery
- Treatment of choice in colonic inertia: total colectomy with ileo-rectal anastomosis.

Before surgery....

- **Repeat transit study**

- mean interval of 14m between 2 studies
- 3/12 patients excluded for surgery

N transit studies	success rate (2-96m FU)
≥ 2 studies	9/9 (100%)
1 study	13/21 (62%)

Consider temporary loop ileostomy

Consider subtotal colectomy

AGA Medical Position Statement on Constipation,
Gastroenterology 2013;144:211-217

Constipation 2nd case

MN, 1981

- Constipation since her infancy with 2 bowel movements/week, getting worst when she has stressful periods (Fructose and Metamucil)
- No sign of obstructive defecation
- Normal colonoscopy in 2002 (21 years old)
- In **2004** she lose weight (35.5 kilos, 1.53 cm, BMI 15 kg/m²)
- She consults in **2005** for constipation (bowel movement every 4 days), abdominal bloating and discomfort while taking Fructose 2x/day

MN, 1981

- Laboratory normal, except for a moderate higher morning blood cortisol and a lower IgF1, consistent with a previous eating disorder
- She works as a nurse and she takes no constipating drug
- Transit time of 110 hours (uniform distribution within the colon)
- Normal digital rectal examination
- Proposed treatment: Zelmac (no effect), then Transipeg + Padma Lax + acupuncture with a moderate improvement

MN, 1981

- **2006:** fluctuant symptoms with some constipation periods of 3-4 days, intermittent abdominal bloating (no effect of Flatulex, Infloran)
- **2007:** worsening of abdominal bloating and pain with aggravation in stand up position, abdominal CT showing a dilated right colon and coprostasis
- **2007:** hospitalized at CHUV (main symptoms: bloating and abdominal pain): enteroclysis CT normal, colonoscopy and gastroscopy normal, normal biological tests, breath test suggesting lactose intolerance and psychological examination suggesting a depressive reaction secondary to worsening somatic pain → Diagnose: Irritable bowel syndrome and lactose intolerance.

MN, 1981

- Therapeutic suggestions CHUV: abdominal massage, abdominal TENS, Citalopram, avoid dairy products, Transipeg et Padma Lax (bowel movements every 2 days)
- **2008**: persistence of abdominal bloating and pain, she stops working, persistence of the depression reaction (Fluoxetine)
- Progressive severe symptoms with no response to various medications (Debridate, Duspatalin, Neostigmine, hydro-colonotherapy, Somatostatin, Dulcolax)

What would you do?

MN,1981

- **July 2008:** left colectomy (resection of 70 cm dilated sigmoid and descending colon, hystopathologically normal)
- **November 2008:** abdominal bloating +++, bowel movement every day with Laxoberon 5-10 drops/day
- **2008:** normal anorectal manometry
- **January 2009:** normal small bowel manometry:
 - Probably “*functional gastrointestinal condition*” (no histological lesion, worsening with stress) secondary to long standing abuse of medication and/or behavioral disturbance
 - No enteric pathology
- **April 2009:** right colectomy and adhesiolysis

Segmental colectomy

- 100% failure rates *Pretson DM. BJS 1984, Gray EJ. Ann Surg 1971*
- Segmental colonic transit studies
 - n=18 63% satisfaction *de Graaf EJ. BJS 1996*
 - n=40 n=3 IRA after 1 year *You YT. Ann Surg 1998*
 - n=28 median FU 50 month
n=5 failure (18%) *Lundin E. BJS 2002*
- Deteriorate with time *Kamm MA. Int J Colorectal Dis 1991*
Knowles CH Ann Surg 1999

Trial ileostomy ?

MN, 1981

- **June 2009:** 3 mm ileo-rectal stenosis, endoscopically dilated to 15 mm in one session → perforation, temporary ileostomy
- She still complains of abdominal bloating during the ileostomy period even if normal ileostomy transit
- Restoration of continuity in **Sept 2009**
- **2010:** her 5th surgery: adhesiolysis because of abdominal pain and bloating
- 2010: several analgesics: Lyrica, Tramal, Oxycontin

MN, 1981

- **Good improvement since 2011** when she starts wearing an abdominal support belt and she starts dating her future husband.
- She gives birth to a healthy boy in **Oct 2013**
- **2014:** she has no complains (still wearing a support belt) and she works at partial time

What can we learn from this case?

- Is it constipation or IBS with constipation?
- “Functional gastrointestinal disorder” secondary to long standing laxative abuse ?
- Abdominal bloating becomes a leading symptom
- Again: left colectomy as initial treatment
- Again: complete constipation work-up after the first surgery
- Place of the newer constipation medicine (Constella, Amitiza)?
- Large caliber anastomotic dilation during one endoscopic season (3mm → 15 mm)

Constipation vs IBS with constipation

Rome III criteria for constipation

Symptoms for ≥ 6 months and ≥ 2 of the following for more than $\frac{1}{4}$ of defecations during the past 3 months:

- Straining
- Lumpy or hard stools
- Sensation of incomplete evacuation
- Sensation of anorectal obstruction/blockade
- Manual maneuvers to facilitate defecations; < 3 defecations/week
- Loose stools are not present and there are insufficient criteria for IBS

Rome III criteria for IBS with constipation

Recurrent abdominal pain or discomfort at least 3 days per month in the past 3 months associated with two or more of the following:

- Improvement with defecation
- Onset associated with change in frequency of stool
- Onset associated with change in form (appearance) of stool
- $< 25\%$ of bowel movements were loose stools

Constipation vs IBS with constipation

Rome III criteria for constipation

Symptoms for ≥ 6 months and ≥ 2 of the following for more than $\frac{1}{4}$ of defecations during the past 3 months:

- Straining
- Lumpy or hard stools
- Sensation of incomplete evacuation
- Sensation of anorectal obstruction/blockage
- Manual maneuvers to facilitate defecations; < 3 defecations per week
- Loose stools are not present and there are insufficient criteria for IBS

Rome III criteria for IBS with constipation

Recurrent abdominal pain or discomfort at least 3 days per month in the past 3 months

1. Probably “functional abdominal disorder” secondary to long standing laxative abuse
2. Bloating in a patient with possibly weak abdominal wall

Two or more of the following: (1) Defecation with change in abdominal pain or discomfort (2) Change in stool form (3) Change in stool frequency (4) Stool movements were

Chronic stimulant laxative use

	Group 1 (n = 29) (%)	Group 2 (n = 26) (%)
Loss of haustral marking	8 (27.6)	0*
Colonic dilatation	13 (44.8)	6 (23.1)
Redundancy of colon	10 (34.5)	5 (19.2)

*p < 0.005.

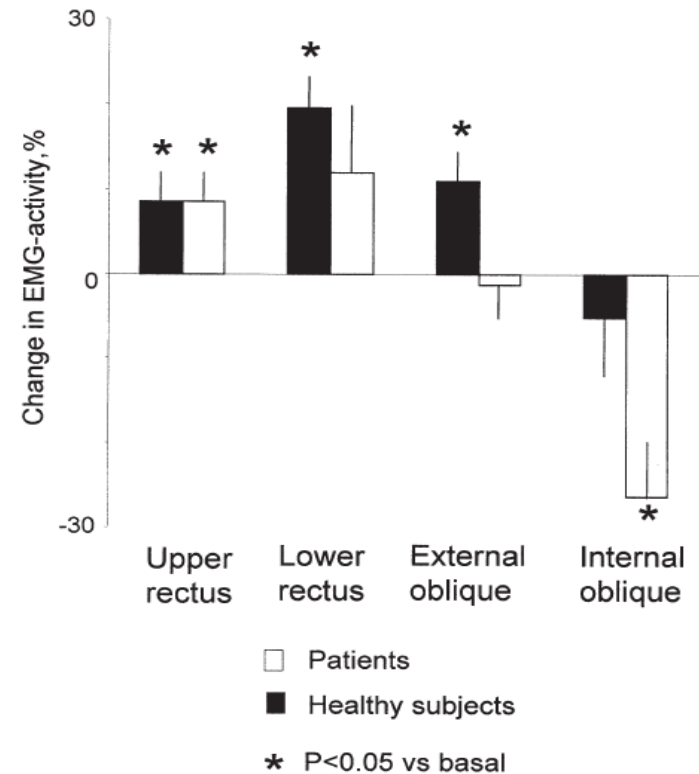

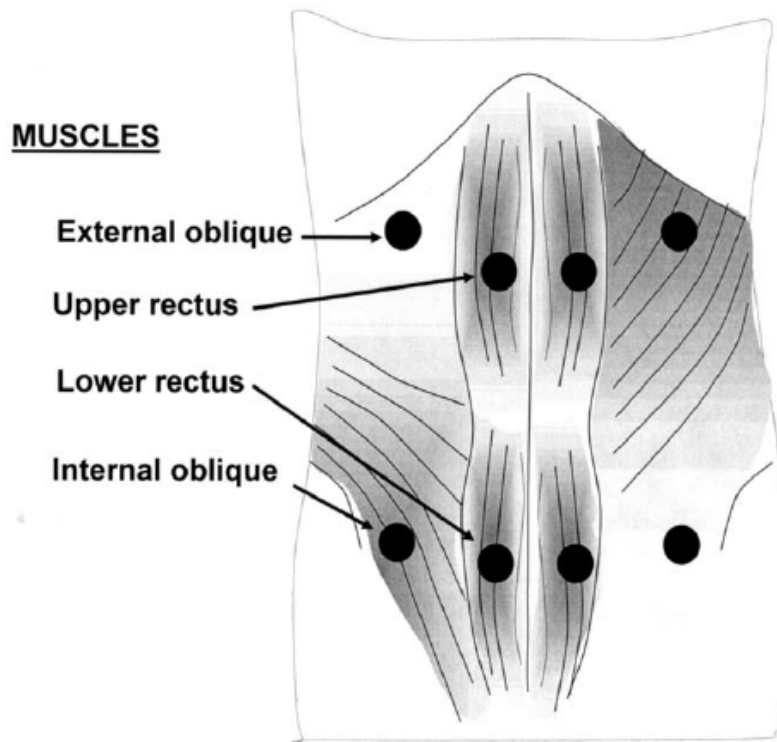

Effects of long standing laxative use:

- Stimulant laxatives cause increased activity of the intrinsic neuronal pathways of the colon. Later, neuronal damage and death occurs, resulting in denervation injury and atrophy of the colonic smooth muscle
- Animal studies suggest that chronic stimulant laxative intake results in degeneration of colonic myenteric plexus

Abdominal bloating

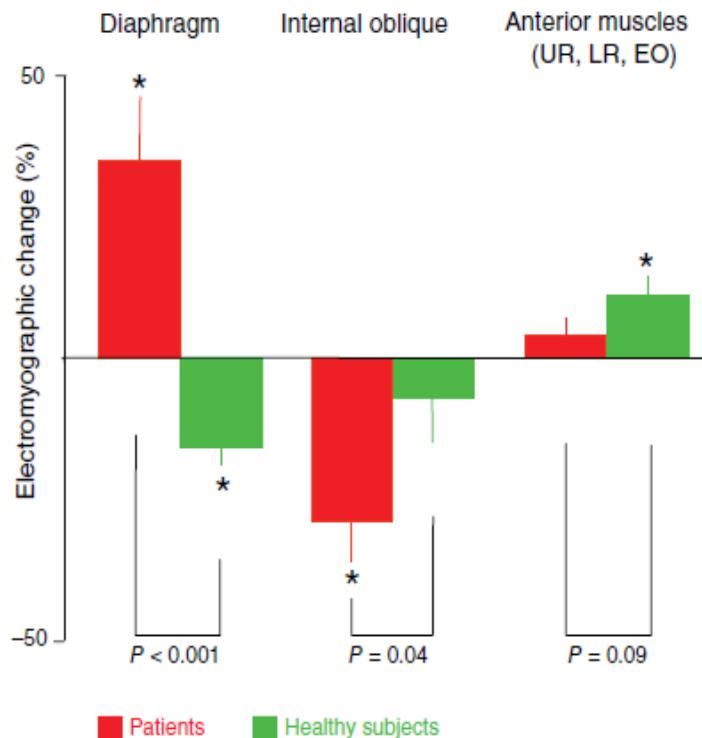

Dysfunction of the abdominal muscle strap

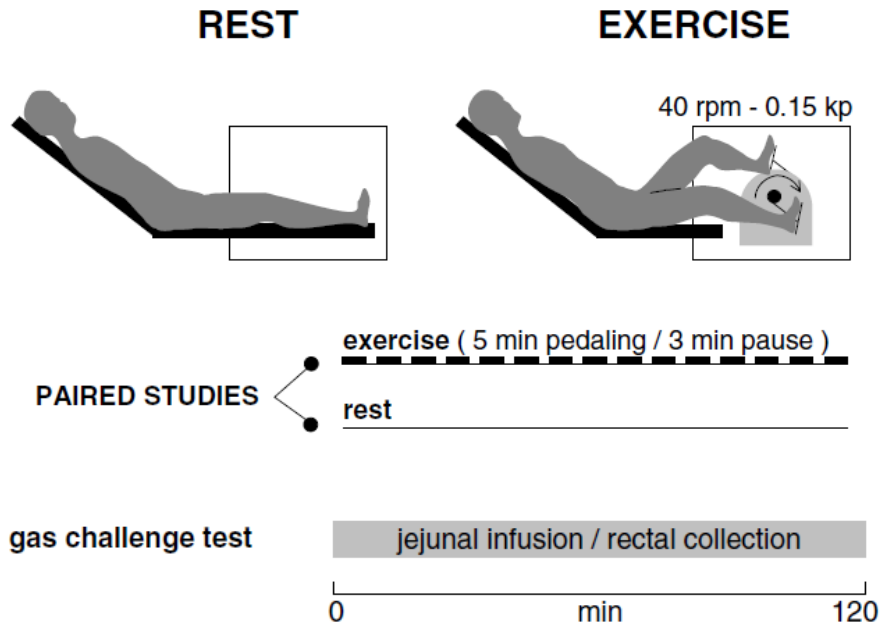

- The same volume load produced significantly more abdominal distention in patients with bloating.
- The decrease in activity of the internal oblique correlated with increments in girth
- The colonic gas distribution was similar in patients and healthy subjects

Abdomino-phrenic dyssynergia

47 patients with IBS without diarrhea
 12 normal subjects
 9 patients with intestinal dysmotility

Abdominal wall and exercises

8 patients

New constipation medication: Constella

804 patients, NNT=5

Chey WD et al. Am J Gastroenterol 2012;107:1702-1712

Endoscopic balloon anastomotic dilation

Study (first author)	Patients n	Type of dilatation	Success (%)	Average number of dilatations
Araujo, 2008 [5]	24	endoscopic	22 (92)	2.3
Di Giorgio, 2004 [6]	30	endoscopic	30 (100)	2.6
Venkatesh, 1992 [12]	17	endoscopic	16 (96)	–
Johansson, 1996 [9]	14	endoscopic	12 (86)	3.7
Skreden, 1987 [10]	12	endoscopic	10 (83.3)	2
Ambrosetti, 2008 [4]	12	endoscopic	12 (100)	1.4

Delaunay-Tardy, 2003 [13]	27	endoscopic	21 (77.1)	2.0
Pietropaolo, 1990 [12]	42	endoscopic vs. bougienage	41 (97.6)	–
Suchan, 2003 [15]	94	endoscopic & fluoroscopic	67% (63/94)	2.5
Di, 2005 [8]	17	fluoroscopic	71% complete 29% partial	1.0

805 procedures, 1.4% complications: 1.1% perforations, abscesses 0.2% and pyrexia 0.1%

Recurrence: 4-20%

Endoscopic balloon anastomotic dilation

ASGE: “The rule of 3 has been used when deciding how much to dilate a stricture with a bougie dilator in 1 session. This rule states that after moderate resistance is encountered, no more than 3 dilators of progressively increasing diameter should be passed in that session.”

ASGE Tools for endoscopic stricture dilation; Gastrointestinal Endoscopy 2013;Vol78,No3

Prospective trial randomized patients with symptomatic benign postoperative anastomotic colorectal strictures :

- dilation with either 18 mm TTS balloon vs dilation with an over-the-wire 35 mm pneumatic balloon

Results:

- success in all patients without complications
- 1.6 sessions vs 2.6 session (p=0.009)
- longer response duration : 560 days vs 245 days, p=0.016
